The recent synthesis and study of two-dimensional electron fluids has produced a new class of materials, namely the high-mobility electron fluids, where the electrons have the high mobilities of typical semiconductors but the mobility of the holes is typically much lower. While these materials can be many tens of times more conductive than typical semiconductor devices, the origin of their high mobilities is unknown. The extremely short mean-free path of the carriers suggests that Coulomb scattering plays a negligible role in the transport and that, unlike in conventional semiconductors, disorder is the dominant scattering mechanism. Here we demonstrate that, despite the lack of any appreciable disorder, these high-mobility electron fluids exhibit extremely strong anomalous transport and magnetotransport effects, as well as a strong negative magnetoresistance. These results provide compelling evidence for strong electron-electron interactions. The similarity of the properties of these fluids to those of quantum-Hall systems, which are often modeled in terms of Coulomb interactions, suggests that the strong interaction between electrons in high-mobility electron fluids is Coulombic and originates from a small but nonzero carrier density. A randomized trial comparing adjuvant therapy with and without intraperitoneal cisplatin after optimal cytoreductive surgery in patients with pseudomyxoma peritonei.

A multi-institutional randomized trial was performed to compare adjuvant therapy with or without intraperitoneal cisplatin for patients with pseudomyxoma peritonei who underwent optimal cytoreductive surgery. In all, 119 patients were randomly assigned to receive 2d92ce491b
