Carotid intraluminal ultrasound (US) and digital subtraction cerebral angiography (DSA) are both considered diagnostic modalities for the assessment of carotid stenosis. However, they are performed in a manner that may limit their reliability. This study assessed a novel technique combining both diagnostic techniques with specific details of the bifurcation. Thirty patients with carotid stenosis of 50% or more underwent assessment with the 3D Neuro-Siemens IDEUS system and the Simplex system, which is a vascular imaging unit on the same Siemens Somatom Spirit. The results of the 2 modalities were compared, and the results of angiography were confirmed by a vascular surgeon. The results of IDEUS were as follows: correct identification of the plaque (78.2%); successful identification of the plaque (89.1%); and identification of the occluded plaque (64.3%). Assessment of the carotid bifurcation with DSA alone is technically difficult and may lead to inaccurate results. IDEUS may be a reliable and practical alternative to DSA for the assessment of carotid stenosis.[Purification and identification of a potent inhibitor of cAMP phosphodiesterase in mouse liver]. Using a trifluoperazine affinity column, a potent inhibitor of cAMP phosphodiesterase, was purified to homogeneity from the soluble fraction of mouse liver. The inhibitor was found to

The reaction mechanism of cobalt(i)-catalyzed lactone reduction is presented, on the basis of a combination of experiments and DFT calculations. The reduction of lactones by Ph(3)P is accompanied by the formation of a Co(2+) species in which the Co(2+) center is coordinated by a phosphane ligand, with the methyl group pointing toward the cobalt atom. Subsequently, a monoanionic alkyl cobalt(III) species is formed, which is proposed to be responsible for the subsequent reduction of the lactone.,G., [*Numerical ranges of operators on complex Hilbert spaces*]{}, Math.
