Surgical procedures typically involve the creation of a pathway through the skin to the underlying tissues and organs, through which surgical instruments are introduced for performing the desired surgical procedure. During such procedures, dilators, catheters, needles, and other instruments may be introduced through the pathway to be used in the procedure. Dilators have been used to expand a pathway through the skin to the underlying tissues and organs. For example, U.S. Pat. No. 5,433,708 to Losano, Sr. et al. describes dilator assemblies used to dilate the pathway. However, the use of such dilators may pose a number of disadvantages. Most importantly, the insertion of such dilators into the pathway to be expanded often requires the use of a smaller, high speed motor. Such motors may be used to rotate the dilator but, in many cases, the motor is unable to operate at the required speed to provide high enough torque to move the dilator back out of the pathway before the pathway is expanded. When the dilator is unable to back out of the pathway before the pathway is expanded, the dilator may become stuck inside the pathway. As a result, the procedure may have to be delayed while the surgeon extracts the stuck dilator. This disadvantage may be exacerbated when the surgeon is operating in a small or difficult to access surgical site. Furthermore, when the surgeon finds that the dilator has become stuck ba244e880a
