It is the best tool out there. 20 Sep 2014 Browsing the documentation page of RESX-Translator on codeplex.com, I've found a very useful feature that I hadn't known about: to perform the translation by list. The English text is placed in one listbox and the translated texts in another. The user can switch, by clicking on a button, between English and the different target languages. This is particularly useful in order to have a preview of the translation and avoid any mistakes in the settings of the translation. A working example can be found in the gallery of the documentation page: 09e8f5149f

You can run ResX-Translator from Visual Studio menu: ResX-Translator\ResX-Translator. Get all string resource files from your Project: Open the ResX-Translator Window and switch to the Project tab. All string resources are available here.1. Field of the Invention This invention relates to a slidable ejector apparatus for use in a recording apparatus. More particularly, it relates to a recording apparatus of the type wherein a recording head is reciprocated across the surface of a recording medium for multi-printing, the head including a moving head unit having a plurality of recording electrodes, and the apparatus comprises an ejector arranged to eject recording liquid from a plurality of ejection orifices arranged at a predetermined interval along the moving head unit. 2. Description of the Prior Art It is known to use a rotary polygonal turret to feed a recording medium along a predetermined path so that a multi-printing recording operation is carried out. In such a system, the recording head may be reciprocated along the path defined by the turret. In order to perform a multi-printing operation as mentioned above, it is necessary to eject ink from the discharge orifices along the moving head unit at predetermined intervals. To this end, it is known to incorporate an ejector into the moving head unit. However, it is impossible to incorporate an ejector by simply adjusting its position along the path, because it is impossible to make uniform the positional relationship of the discharge orifices with respect to the moving head unit. Therefore, it has been necessary to provide a complex adjusting mechanism for the ejector. However, the provision of an adjusting mechanism is not preferable because it requires additional parts and spaces, and makes the moving head unit more expensive. Further, the need for a more complex mechanism for adjusting the position of the ejector results in a greater possibility of malfunction. On the other hand, it is known that the distance between the discharge orifices and the next discharge orifices should be made uniform. As shown in FIG. 1, a recoding head 1 is movable along a straight path in an XY plane defined by an axis Z and a moving direction. A recording medium M is moved along the path by a recording medium moving device (not shown). The recording head 1 has a moving head unit 11 and a stationary head unit 13. The moving head unit 11 includes a plurality of recording electrodes 12 for forming desired dots and a plurality
